

What Is Propagation

Propagation means to reproduce an organism through natural or unnatural processes. The idea behind controlling cannabis propagation is to produce cannabis crops that contain uniform plant sizes and genetics. When it comes to Cannabis plants, the Propagation Stage is considered the 3rd happiest moment for most growers.

The 1st happiest moment is harvesting your hard earned fruits or flowers and the 2nd happiest moment is knowing that your plant is a female.

Propagating your Cannabis plants can happen in two different ways: by germinating seeds or by taking cuttings, or “clones”, from existing Cannabis plants.

Both ways have their advantages and disadvantages but each are essential to every growers playbook.

For the most part, seed germinating and cloning both require similar equipment and environments to get the job done, so we will be going over both of them in great detail.
